02 Propositional logic I

- 1 Syntax of propositional logic
- 2 Semantics of propositional logic
- 3 Satisfiability and validity

Syntax of propositional logic

Abstract syntax of well-formed propositional formulae:

$\varphi := a \mid (\neg\varphi) \mid (\varphi \wedge \varphi)$. A proposition is a sentence like $p \mid (p \mid q)$
An atomic proposition is like p
原子命题是最小的命题, 内部不包含更小的命题

where AP is a set of (atomic) propositions (Boolean variables) and $a \in AP$.
We write $PropForm$ for the set of all propositional logic formulae.
formulae由ap构成

Syntactic sugar:

\perp	$:= (a \wedge \neg a)$	unconditional false
\top	$:= (a \vee \neg a)$	unconditional true
$(\varphi_1 \vee \varphi_2)$	$:= \neg((\neg\varphi_1) \wedge (\neg\varphi_2))$	
$(\varphi_1 \rightarrow \varphi_2)$	$:= ((\neg\varphi_1) \vee \varphi_2)$	$\neg(1 \wedge (\neg 2))$
$(\varphi_1 \leftrightarrow \varphi_2)$	$:= ((\varphi_1 \rightarrow \varphi_2) \wedge (\varphi_2 \rightarrow \varphi_1))$	
$(\varphi_1 \oplus \varphi_2)$	$:= (\varphi_1 \leftrightarrow (\neg\varphi_2))$	

- Examples of **well-formed formulae**:

- $(\neg a)$
- $(\neg(\neg a))$
- $(a \wedge (b \wedge c))$
- $(a \rightarrow (b \rightarrow c))$

- We **omit parentheses** whenever we may restore them through operator precedence:

binds stronger

$\neg \quad \wedge \quad \vee \quad \rightarrow \quad \leftrightarrow$

- We will also use the “big” Boolean notation, e.g.

$$\bigwedge_{i=1}^5 x_i$$

is defined as

$$x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 .$$

02 Propositional logic I

- 1 Syntax of propositional logic
- 2 Semantics of propositional logic
- 3 Satisfiability and validity

Semantics: Assignments

Structures for propositional logic:

- The **domain** is $\mathbb{B} = \{0, 1\}$.
- The **interpretation** assigns Boolean values to the variables:

$$\alpha : AP \rightarrow \{0, 1\}$$

We call these special interpretations **assignments** and use **Assign** to denote the set of all assignments.

Example: $AP = \{a, b\}, \alpha(a) = 0, \alpha(b) = 1$

即对atomic
proposition赋值

Equivalently, we can see an **assignment** α as a set of variables $(\alpha \in 2^{AP})$, defining the variables from the **set to be true** and the others false.

Example: $AP = \{a, b\}, \alpha = \{b\}$ assignment可以定义为真值集合

An **assignment** can also be seen as being of type $\alpha \in \{0, 1\}^{AP}$, if we have an **order** on the propositions.

Example: $AP = \{a, b\}, \alpha = 01$

如果ap有顺序的话, assignment可以被视为ap的取值序列

Only the projected assignment matters...

- Let $\alpha_1, \alpha_2 \in \text{Assign}$ and $\varphi \in \text{PropForm}$.
- Let $AP(\varphi)$ be the atomic propositions in φ .
- Clearly $AP(\varphi) \subseteq AP$.
- **Lemma:** if $\alpha_1|_{AP(\varphi)} = \alpha_2|_{AP(\varphi)}$, then

Projection

$$(\alpha_1 \text{ satisfies } \varphi) \text{ iff } (\alpha_2 \text{ satisfies } \varphi)$$

- We will assume, for simplicity, that $AP = AP(\varphi)$.

Semantics I: Truth tables

- **Truth tables** define the **semantics (=meaning)** of the **operators**.
They can be used to define the semantics of formulae inductively over their structure.
- Convention: **0** = false, **1** = true

p	q	$\neg p$	$p \wedge q$	$p \vee q$	$p \rightarrow q$	$p \leftrightarrow q$	$p \oplus q$
0	0	1	0	0	1	1	0
0	1	1	0	1	1	0	1
1	0	0	0	1	0	0	1
1	1	0	1	1	1	1	0

Each possible assignment is covered by a line of the truth table.

α satisfies φ iff in the **line for α** and the **column for φ** the entry is 1.
satisfy即assignment取值可使formulae为真

Q: How many binary operators can we define that have different semantics?

A: 16

因为binary operators的输入共有4种类可能: 00, 01, 10, 11

所以对应不同的semantics(即真值表的可能取值)为 2^4

同理, three parameter operator的semantics为 2^8

Semantics I: Example

- Let φ be defined as $(a \vee (b \rightarrow c))$.
- Let $\alpha : \{a, b, c\} \rightarrow \{0, 1\}$ be an assignment with $\alpha(a) = 0$, $\alpha(b) = 0$, and $\alpha(c) = 1$.
- Q: Does α satisfy φ ?
- A1: Compute with truth table:

a	b	c	$b \rightarrow c$	$a \vee (b \rightarrow c)$
0	0	0	1	1
0	0	1	1	1
0	1	0	0	0
0	1	1	1	1
1	0	0	1	1
1	0	1	1	1
1	1	0	0	1
1	1	1	1	1

Semantics II: Satisfaction relation

Satisfaction relation: $\models \subseteq \text{Assign} \times \text{PropForm}$ $\text{Assignment} \models \text{PropForm}$

Instead of $(\alpha, \varphi) \in \models$ we write $\alpha \models \varphi$ and say that

- α satisfies φ or
- φ holds for α or
- α is a model of φ .

\models is defined recursively:

$\alpha \models p$	iff	$\alpha(p) = \text{true}$
$\alpha \models \neg \varphi$	iff	$\alpha \not\models \varphi$
$\alpha \models \varphi_1 \wedge \varphi_2$	iff	$\alpha \models \varphi_1$ and $\alpha \models \varphi_2$
$\alpha \models \varphi_1 \vee \varphi_2$	iff	$\alpha \models \varphi_1$ or $\alpha \models \varphi_2$
$\alpha \models \varphi_1 \rightarrow \varphi_2$	iff	$\alpha \models \varphi_1$ implies $\alpha \models \varphi_2$
$\alpha \models \varphi_1 \leftrightarrow \varphi_2$	iff	$\alpha \models \varphi_1$ iff $\alpha \models \varphi_2$

Note: More elegant but semantically equivalent to truth tables.

- Let φ be defined as $(a \vee (b \rightarrow c))$.
- Let $\alpha : \{a, b, c\} \rightarrow \{0, 1\}$ be an assignment with $\alpha(a) = 0$, $\alpha(b) = 0$, and $\alpha(c) = 1$.
- Q: Does α satisfy φ ?

A2: Compute with the satisfaction relation:

$$\alpha \models (a \vee (b \rightarrow c))$$

$$\text{iff } \alpha \models a \text{ or } \alpha \models (b \rightarrow c)$$

$$\text{iff } \alpha \models a \text{ or } (\alpha \models b \text{ implies } \alpha \models c)$$

$$\text{iff } 0 \text{ or } (0 \text{ implies } 1)$$

$$\text{iff } 0 \text{ or } 1$$

$$\text{iff } 1$$

Semantics III: The algorithmic view

- Using the satisfaction relation we can define an **algorithm** for the problem to decide whether an assignment $\alpha : AP \rightarrow \{0, 1\}$ is a model of a propositional logic formula $\varphi \in PropForm$:

```
Eval( $\alpha, \varphi$ ) {  
    if  $\varphi \equiv a$  return  $\alpha(a)$ ;  
    if  $\varphi \equiv (\neg \varphi_1)$  return not Eval( $\alpha, \varphi_1$ );  
    if  $\varphi \equiv (\varphi_1 \text{ op } \varphi_2)$   
        return Eval( $\alpha, \varphi_1$ ) [op] Eval( $\alpha, \varphi_2$ );  
}
```

- Equivalent to the \models relation, but from the algorithmic view.
- Q: Complexity? A: Polynomial (time and space).

- Recall our example

- $\varphi = (a \vee (b \rightarrow c))$

- $\alpha : \{a, b, c\} \rightarrow \{0, 1\}$ with $\alpha(a) = 0$, $\alpha(b) = 0$, and $\alpha(c) = 1$.

- $$\begin{aligned} \text{Eval}(\alpha, \varphi) &= \text{Eval}(\alpha, a) \text{ or } \text{Eval}(\alpha, b \rightarrow c) = \\ &0 \text{ or } (\text{Eval}(\alpha, b) \text{ implies } \text{Eval}(\alpha, c)) = \\ &0 \text{ or } (0 \text{ implies } 1) = \\ &0 \text{ or } 1 = \\ &1 \end{aligned}$$

- Hence, $\alpha \models \varphi$.

- Intuition: each formula specifies a set of assignments satisfying it.
- Remember: *Assign* denotes the set of all assignments.
- Function $\text{sat} : \text{PropForm} \rightarrow 2^{\text{Assign}}$ PropForm|=2^Assign (使PropForm成立的assignment的实际取值)
 (a formula \rightarrow set of its satisfying assignments)

- Recursive definition:

sat()即使PropForm取值为真的assignment

$$\text{sat}(a) = \{\alpha \mid \alpha(a) = 1\}, \quad a \in AP$$

$$\text{sat}(\neg \varphi_1) = \text{Assign} \setminus \text{sat}(\varphi_1)$$

$$\text{sat}(\varphi_1 \wedge \varphi_2) = \text{sat}(\varphi_1) \cap \text{sat}(\varphi_2)$$

$$\text{sat}(\varphi_1 \vee \varphi_2) = \text{sat}(\varphi_1) \cup \text{sat}(\varphi_2)$$

$$\text{sat}(\varphi_1 \rightarrow \varphi_2) = (\text{Assign} \setminus \text{sat}(\varphi_1)) \cup \text{sat}(\varphi_2)$$

- For $\varphi \in \text{PropForm}$ and $\alpha \in \text{Assign}$ it holds that

$$\alpha \models \varphi \quad \text{iff} \quad \alpha \in \text{sat}(\varphi)$$

Satisfying assignments: Example

$$\text{sat}(a \vee (b \rightarrow c)) =$$

$$\text{sat}(a) \cup \text{sat}(b \rightarrow c) =$$

$$\text{sat}(a) \cup ((\text{Assign} \setminus \text{sat}(b)) \cup \text{sat}(c)) =$$

$$\{\alpha \in \text{Assign} \mid \alpha(a) = 1\} \cup$$

$$\{\alpha \in \text{Assign} \mid \alpha(b) = 0\} \cup$$

$$\{\alpha \in \text{Assign} \mid \alpha(c) = 1\} =$$

$$\{\alpha \in \text{Assign} \mid \alpha(a) = 1 \text{ or } \alpha(b) = 0 \text{ or } \alpha(c) = 1\}$$

Extensions of \models

2^{Assign} : 使PropForm成立的assignment的实际取值情况

- We define $\models \subseteq 2^{\text{Assign}} \times \text{PropForm}$ by
assignment的实际取值情况 \models PropForm

$$T \models \varphi \text{ iff } T \subseteq \text{sat}(\varphi)$$

for formulae $\varphi \in \text{PropForm}$ and assignment sets $T \subseteq 2^{\text{Assign}}$.

Examples: $\{\alpha \in \text{Assign} \mid \alpha(a) = \alpha(c) = 1\} \models a \vee (b \rightarrow c)$
 $\{\alpha \in \text{Assign} \mid \alpha(x_1) = 1\} \models x_1 \vee x_2$

- We define $\models \subseteq \text{PropForm} \times \text{PropForm}$ by
PropForm \models PropForm

$$\varphi_1 \models \varphi_2 \text{ iff } \text{sat}(\varphi_1) \subseteq \text{sat}(\varphi_2)$$

for formulae $\varphi_1, \varphi_2 \in \text{PropForm}$.

Examples: $a \wedge c \models a \vee (b \rightarrow c)$
 $x_1 \models x_1 \vee x_2$

Short summary for propositional logic syntax and semantics

- **Syntax** of propositional formulae $\varphi \in \text{PropForm}$:

$$\varphi := AP \mid (\neg\varphi) \mid (\varphi \wedge \varphi)$$

- **Semantics:**

- **Assignments** $\alpha \in \text{Assign}$:

$$\alpha : AP \rightarrow \{0, 1\}$$

$$\alpha \in 2^{AP}$$

$$\alpha \in \{0, 1\}^{AP}$$

- **Satisfaction relation:**

$$\models \subseteq \text{Assign} \times \text{PropForm}, \quad (\text{e.g., } \alpha \models \varphi)$$

$$\models \subseteq 2^{\text{Assign}} \times \text{PropForm}, \quad (\text{e.g., } \{\alpha_1, \dots, \alpha_n\} \models \varphi)$$

$$\models \subseteq \text{PropForm} \times \text{PropForm}, \quad (\text{e.g., } \varphi_1 \models \varphi_2)$$

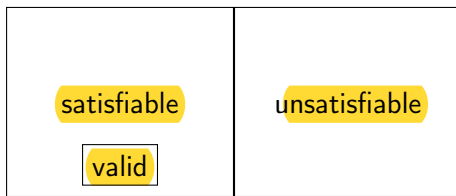

$$\text{sat} : \text{PropForm} \rightarrow 2^{\text{Assign}}, \quad (\text{e.g., } \text{sat}(\varphi))$$

02 Propositional logic I

- 1 Syntax of propositional logic
- 2 Semantics of propositional logic
- 3 Satisfiability and validity

Semantic classification of formulae

- A formula φ is called **valid** if $\text{sat}(\varphi) = \text{Assign}$. 永真式 (任何条件下都为真)
(Also called a **tautology**).
- A formula φ is called **satisfiable** if $\text{sat}(\varphi) \neq \emptyset$.
- A formula φ is called **unsatisfiable** if $\text{sat}(\varphi) = \emptyset$.
(Also called a **contradiction**). 矛盾式 (任何情况下都为假)

- We can write:

- $\models \varphi$ when φ is **valid**
- $\not\models \varphi$ when φ is **not valid** 不是所有情况都能推出
- $\models \neg \varphi$ when φ is **satisfiable** 不是所有情况都会推出非
- $\models \neg \varphi$ when φ is **unsatisfiable**

Examples

■ $(x_1 \wedge x_2) \rightarrow (x_1 \vee x_2)$

■ $(x_1 \vee x_2) \rightarrow x_1$

■ $(x_1 \wedge x_2) \wedge \neg x_1$

is **valid** 永真式

is **satisfiable** 有成立的情况, 是
satisfiable

is **unsatisfiable** 没有成立的情况

- Here are some valid formulae:

- $\models a \wedge 1 \leftrightarrow a$
- $\models a \wedge 0 \leftrightarrow 0$
- $\models \neg\neg a \leftrightarrow a$ (double-negation rule)
- $\models a \wedge (b \vee c) \leftrightarrow (a \wedge b) \vee (a \wedge c)$

- Some more (De Morgan rules):

- $\models \neg(a \wedge b) \leftrightarrow (\neg a \vee \neg b)$
- $\models \neg(a \vee b) \leftrightarrow (\neg a \wedge \neg b)$

The satisfiability problem for propositional logic

- The **satisfiability problem** for propositional logic is as follows:
Given an input propositional formula φ , decide whether φ is satisfiable.
- This problem is decidable but **NP-complete**.
- An **algorithm** that always **terminates** for each propositional logic formula **with the correct answer** is called a **decision procedure** for propositional logic.

Goal: Design and implement such a decision procedure:

Note: A formula φ is valid iff $\neg\varphi$ is unsatisfiable.

- What are the rules to (syntactically) build propositional logic formulas?
- How to interpret propositional logic formulas...
 - ... using truth tables?
 - ... using the satisfaction relation?
 - ... algorithmically by the Eval function?
- How to compute the set of all satisfying assignments recursively by the sat function?
- When is a propositional logic formula valid, satisfiable or unsatisfiable?
